Conclusion

Potassium fertilizer has proven to be extremely important for crop growth on Hunan’s K-deficient upland soils. This has been manifested in higher crop yields, improved crop quality, and increased farmer profit when K fertilizer was applied compared to no K application, but with N and P fertilizer applied at optimal rates.

For the majority of crops grown on these soils, an application of 150 kg K$_2$O/ha was considered to be a minimum to achieve high crop yield and quality, while higher rates often proved better for the high K demanding crops. BCI

### India: Response of Some Rabi Pulses to Boron, Zinc and Sulfate Application in Farmer Fields

Series of field trials were conducted on calcareous soils in the northern part of Bihar. A high percentage of these soils exhibit sulfur (S), boron (B) and zinc (Zn) deficiencies. Test crops were chickpea, lentil and broadbean. Boron application at 2 kg/ha and Zn application at 5 kg/ha on chickpea produced grain yield responses of 750 (60 percent yield increase) and 400 (28 percent yield increase) kg/ha, respectively. Boron application rate of 1 kg/ha increased lentil yields by 300 kg/ha, or 24 percent. Broadbean yield response to S applied at a rate of 40 kg/ha was 700 kg/ha, a 32 percent increase. In addition to yield responses, plant uptake of all three nutrients was increased by fertilization. BCI
